## Abstract

---

Viruses are small tiny droplets of microbes and mostly cause and also create a pandemic situation in the world such as COVID-19. Numerous viruses are reported up to date, and still new ones are coming, which leads to continuous research on finding new diagnostic tests with a novel treatment option. Numerous bioinformatic sites continue updating virus genomes with their cell member structure protein to assist the drug developer in finding the

### Abstract

The segment of the United Nations that deals with the medical aspects of all the different parts of the world, the World Health Organization, on the 3rd of May 2021, professed the ongoing Ebola outbreak to be over. Ebola virus is acknowledged to be the causative agent of Ebola viral disease (EVD) or Ebola fever, which is of a hemorrhagic nature, a viral hemorrhagic disease found in humans in addition to

### Abstract

Currently,SARS-CoV-2(COVID-19)isthedominant disease in the globe. It has resulted into major economic disruption and social disturbance all aroundtheworld.Manyantiviralsareundertrialfor the treatment of the infection. However, efficacy of drugs is often limited due to certain factors associatedwiththedrug.Suchproblemscanbe overcome by using novel drug delivery systems employing nanotechnology. These delivery systems canbemanipulatedforthedesiredsiteofactionand

# Nanotechnology in Malaria Diagnosis

Anita Patel, Jayvadan Patel, Rutvik Patel, and Vidhyut Patidar

**Abstract** Malaria has been accountable for the utmost mortality in the majority of malaria-endemic countries. Even after decades of malaria control campaigns, it still continues as a disease of high mortality owing to inappropriate diagnosis and fast-evolving drug-resistant malarial parasites. For well-organized and economical malaria management, WHO suggests that all malaria-suspected patients must get an appropriate diagnosis before administering drugs. In malaria-endemic countries, routine diagnosis is stuck with technical and infrastructural challenges to laboratories. These laboratories are deficient in standard facilities, expertise, or diagnostic supplies; therefore, therapy is administered based on clinical or self-diagnosis. Traditional methods for diagnosing malaria remain problematic; so, it is thus imperative to develop fast, effective, economical, and accurate techniques for the diagnosis of malaria both in symptomatic and asymptomatic individuals. Nanotechnology-based diagnostics methodologies can boost up detection of malaria at lower parasite levels while presenting a speedy, accurate, sensitive, and easy method. As a result, nanotechnology-based diagnosis tool is fascinating lots of research interest, and a small number of researchers have proposed prospective nanotechnology-based tools for malarial diagnostics which can conquer some of the difficulties currently facing a malarial diagnosis. Future innovation will be essential to make possible the appliance of more sensitive and affordable nanotechnology-based methods for malaria diagnosis in resource-limited settings. Finally, the level of malaria endemicity, the necessity of diagnosis, the experience of the general practitioner, the efficiency of healthcare workers, and budget resources are all factors influencing the choice of malaria-diagnostic technique.

# Nanotechnology in TB Diagnosis

Jayvadan Patel, Anita Patel, and Nisarg Patel

**Abstract** Tuberculosis (TB), caused by the bacterium *Mycobacterium tuberculosis* (Mtb), is still a significant worldwide health issue, and it is the second largest cause of mortality among all infectious diseases (Mtb). TB is most usually associated with the lungs, although it can also damage the kidneys, brain, and spine. The detection of latent tuberculosis infection (LTBI), extrapulmonary tuberculosis (EPTB), drug-resistant tuberculosis (DR-TB), Human immunodeficiency virus (HIV)-associated tuberculosis (TB), and pediatric tuberculosis remains difficult in poor countries. This is mostly due to tuberculosis that has been delayed or misdiagnosed, which is feeding the global epidemic. Because an adequate screening test is currently unavailable, tuberculosis must be diagnosed using traditional methods, despite their limited diagnostic capacity. Nanoparticles have exhibited promising features in improving pharmaceutical distribution, reducing treatment frequency, and improving disease diagnosis. Scientific world believe that nanotechnology has proposed new ways to address residual scientific concerns for TB. Nanotechnology-based concepts have significant potential for diagnosing, treating, and preventing tuberculosis. The creation of antigen/antibody nanocarriers is an intriguing new frontier in the field of diagnostics, with the potential to pave the way for better TB diagnostics. This chapter reviews the current diagnostic techniques for tuberculosis and emphasizes recent advances in nanotechnology-based *Mycobacterium tuberculosis* detection methods.

# Nanotechnology Based Vaccination Approach in Malarial Infection

Priya Patel, Mansi Faladia, Pranav Shah, and Jayvadan Patel

**Abstract** Malaria afflicted an estimated 219 million people in 2017, killing 435,000 people worldwide. This morbidity and mortality burden is the consequence of more than a century of worldwide effort and research aimed at improving malaria prevention, diagnosis, and treatment. Malaria is the most frequent illness in Africa and certain Asian nations, accounting for many indigenous cases. The global malaria fatality rate ranges from 0.3% to 2.2%, and in cases of severe malaria in tropical climatic zones, the rate rises from 11% to 30%. Malaria is caused by a tiny protozoan belonging to the *Plasmodium* species group, which includes various subspecies. *Plasmodium* species can cause illness in humans. *Plasmodium* is a kind of amoeboid intracellular parasite that accumulates malaria pigment (an insoluble metabolite of haemoglobin). Parasites are present in several animals; some in red blood cells and others in tissues. Five *Plasmodium* species can infect humans out of 172 species. These are *Plasmodium malariae*, *Plasmodium falciparum*, *Plasmodium vivax*, *Plasmodium ovale*, and *Plasmodium knowlesi*. The zoonotic malaria *P. knowlesi* has been identified in South-East Asia. Malaria symptoms often occur 10 days to 1 month after infection. Mild symptoms are possible. Some people do not feel ill for up to a year after being bitten by a mosquito. Parasites can survive in the body for years without creating any symptoms. Malaria treatment should begin as soon as feasible. To cure malaria, your doctor will prescribe medication that destroys the parasite. Malaria medications are not effective against some parasites. The kind of medication and duration of therapy is determined by the parasite causing your symptoms. Due to the shortcomings of conventional malaria therapy, a nanotechnology approach has been implemented with vaccine development in various phase trials.

## 7.1 Introduction

### 7.1.1 Focus on Depression and Anxiety

The prevalence of common mental diseases including depression and anxiety has increased over the past few decades, raising concerns about mental health on a global scale (Friedrich 2017, Tariku Seboka et al. 2022). The prevalence of depression in the world increased significantly after the 2020 Covid-19 pandemic (Abbott 2021), markedly even in children and adolescents (Wang et al. 2022). There are considerable negative effects on health due to the growing burden of mental diseases. Up to 25% of patients in general practice have co-occurring depression and anxiety disorders. Approximately 85% of people with depression experience considerable anxiety, and 90% of people with anxiety disorders experience depression (Tiller 2013). Depression is characterized by short-term emotional reactions that hinder daily functioning and are accompanied by symptoms including sadness and frustration, guilt-related sensations, numbness, and loss of interest (Wahed and Hassan 2017). The term “anxiety disorders” refers to a set of mental disorders that are characterized by unpleasant feelings of unease, worry about the future, or

## 17.1 Introduction

The term “microbiota” applies to the entire population of microorganisms in a given location (1). The largest population of microorganisms is the microbiota of the human gut, which is comprised of approximately 100 trillion microorganisms (most of them bacteria, but also fungi, viruses and archaea) (2–7). The collection of genes found in intestinal microorganisms forms a genetic repertoire that is one level above the human genome. (8). The microbiota offers a great deal of help to the host with a variety of physiological functions such as strengthening gut integrity or intestinal epithelium (9), harvesting energy (10), protecting against pathogens (11) and regulating host immunity (12). The human gut microbiota is complex, lively and unique to each individual and influenced by various factors such as diet, age, antibiotic intake, xenobiotics, early life microbiota exposure, changes in hygiene practices, pollution and socioeconomic status (13).

## EPIDEMIOLOGY OF CANCER

The earliest known statement of cancer was written in an Egyptian papyrus around 1600 BC. It was thought to be untreatable until the late 1700s, when anaesthesia, better procedures, and pathological control improved the removal of tumours.<sup>[1]</sup> Cancer is a significant global health issue. A rise in cancer in the coming decades is foreseen by observing global demographic features; around 420 million new cancer cases will be encountered by 2025. Viewing GLOBACon data, 14.1 million new cancer patients were seen and 8.2 million patient deaths owing to cancer were estimated in 2021. According to a 2008 study by the International Agency for Research on Cancer, there could be 13–17 million disease-related deaths worldwide by 2030, vastly increasing since 1975.<sup>[2]</sup> The major

## 18.1 INTRODUCTION

Traditional treatments of cancer such as radiation and chemotherapy therapy are frequently limited by side effects due to a lack of targeted delivery for carrying anticancer drugs to the neoplastic tissues and low drug concentration at the site. To overcome these limitations, subcellular organelle-targeted nanoformulations of anticancer drugs are required. Current developments in nanoformulation-based organelle-targeted drug delivery systems have demonstrated that they can transport drugs to pathological tissues via cell-membrane targeting and release drugs in the cytoplasm (1–3). To be effective, drug nanoparticles (NPs) must enter the cytoplasm of the targeted cell and gain access to a specific organelle such as endosome/lysosome, endoplasmic reticulum (ER), mitochondrion, nucleus, nucleolus, Golgi apparatus (GA), proteasomes and peroxisomes. (4). Organelle-specific delivery has emerged as a key strategy for targeted drug delivery research for cancer theranostics (5).

Organelles are critical for cell function (6–15). Mitochondria are known as the powerhouse of the cells; they are in charge of the adenosine triphosphate (ATP) synthesis from food, calcium ion cycle and apoptosis regulation. The lysosome is involved in digestion, autophagy and cellular defense. Protein synthesis and transportation are facilitated by the endoplasmic reticulum and Golgi apparatus.

# 21 Commercialization Challenges of Tumor Microenvironment–Responsive Nanoplatforms

## 21.1 INTRODUCTION

Nanomedicines are multifaceted engineered nanoscale structures and are extensively used in the treatment and targeting of diseases because of their numerous therapeutic benefits (1). Since the last decade, nanotechnology has been considered a revolutionary technology due to its applicability in multiple fields, including medicine. Due to numerous anticipated beneficial effects, nanomedicines have attracted attention from scientists around the globe. These benefits include protection of the active entity from degradation, enhanced solubility and bioavailability, superior pharmacokinetics, reduced toxicity, enhanced therapeutic efficacy, decreased drug immunogenicity and, most importantly, capability of delivering the drug at the target site (2). Due to exhaustive pharmaceutical research, an increasing number of products containing nanomaterials with different applications, especially with tumors, have surfaced. The use of nanotechnology in the development of new medicines is now part of research around the globe which is capable of providing new and innovative medical solutions to address unmet medical needs (3). However, the definition of nanomaterials has been controversial among various scientific and international regulatory corporations (4). Several opinions come out to agree on a consensual definition of nanomedicines which in turn based on the fact that nanomaterials possess different physicochemical properties than those of their conventional equivalents, due to their small size, charge and stability (5). These physicochemical properties provide a set of opportunities in the development of drug products; however, their safety issues are still major concerns. The physicochemical properties of the nanomedicines which usually alters the pharmacokinetics of drug moiety like absorption (potential to cross biological barriers), effective distribution, elimination and metabolism and their toxic properties which may help in establishing the concerns over the application of the nanoformulations (6). Several nanomedicine products have been approved by the European Medicines Agency (EMA) and the US Food and Drug Administration (FDA) for various therapeutic indications (7). In general, high therapeutic efficacy and safety are the two primary factors for a product in order to qualify as commercially successful. But most nanomedicines fail to meet these requirements; hence their successful commercialization is hampered to a large extent. The limited clinical success of nanomedicines
